Introduction

Project Title: 7achi social media app

Research Question / Problem Statement: How can a simple web application be designed to manage user accounts and posts in an organized and scalable way using a Django-based backend system?

Objective of the Project: To build a basic social media web application using Django that allows users to register, log in, create posts, and view content in a structured feed.

Expected Outcome: A functional web application demonstrating core Django concepts such as user authentication, database models, and operations for posts.

Methodology

Approach to Problem Solving: The application is designed as a basic social media system where user-generated content is stored and managed through database-backed models. Users can register, log in, and create posts, while the system handles storing, retrieving, and displaying data using Django's built-in authentication and ORM. Core operations such as creating accounts, submitting posts, and viewing content are managed through standard request handling and basic SQLite database queries, ensuring that user interactions are processed and reflected in real time.

Control flow:

START → initialize the social media system and load the database models

USER registers or logs in → create a new account or authenticate existing user using Django authentication

USER creates a post → take post content input → store it in the database using Django models

USER views feed → retrieve posts from database → display posts to the user in chronological order

USER interacts with system → (like, comment, or refresh feed) → update or fetch data from database accordingly

REPEAT process while user is active → continue handling requests and database operations

END → user logs out or closes the application
